

# Options - One-Page Reference

Standard academic notation (Hull / Black-Scholes). Payoffs per share; x100 for one contract.

## Variables

|       |                                                                    |
|-------|--------------------------------------------------------------------|
| S     | underlying price. $S_0$ = spot now,<br>$S_T$ = price at expiration |
| K     | strike (older texts: X or E)                                       |
| c, p  | European call / put premium                                        |
| C, P  | American call / put premium                                        |
| T     | time to expiry (yrs); $\tau = T - t$                               |
| r     | risk-free rate (cont. compounded)                                  |
| sigma | volatility                                                         |
| q, D  | dividend yield / PV of dividends                                   |
| N(.)  | standard-normal CDF                                                |

## Payoff at expiry (profit, per share)

|            |                        |
|------------|------------------------|
| Long call  | $\max(S_T - K, 0) - c$ |
| Short call | $c - \max(S_T - K, 0)$ |
| Long put   | $\max(K - S_T, 0) - p$ |
| Short put  | $p - \max(K - S_T, 0)$ |

Pattern: long = intrinsic - premium;  
short flips the sign. Calls use  $S_T - K$ ,  
puts use  $K - S_T$ . Rigorous profit compounds  
the premium: ... -  $c * e^{-(rT)}$ .

## Put-call parity (European, no div.)

$$c + K * e^{-(rT)} = p + S_0$$

Rearranged:  $c - p = S_0 - K * e^{-(rT)}$ .  
Long call + short put at same K =  
a synthetic forward on the stock.  
With dividends, use  $S_0 - D$  in place of  $S_0$ .

## The Box Spread (synthetic loan)

Pick  $K_1 < K_2$ , same expiry. Stack two verticals:

- Bull call spread: long call  $K_1$ , short call  $K_2$
- Bear put spread: long put  $K_2$ , short put  $K_1$

Combined payoff for ANY  $S_T$ :

$$\begin{aligned} &\max(S_T - K_1, 0) - \max(S_T - K_2, 0) \\ &+ \max(K_2 - S_T, 0) - \max(K_1 - S_T, 0) = K_2 - K_1 \end{aligned}$$

$S_T$  terms cancel -> fixed payoff = a

zero-coupon bond. No-arbitrage cost today:

$$\text{Box value} = (K_2 - K_1) * e^{-(rT)}$$

- Long box (pay now, collect  $K_2 - K_1$  later)  
= LENDING at the implied rate.
- Short box (collect now, pay  $K_2 - K_1$  later)  
= BORROWING.

Keep it risk-free: European cash-settled index  
options (SPX/XSP) - American can be assigned  
early and break the box. Hold to expiry.

## Worked examples

### 1. Long call - $K=100$ , $c=4$ :

|             |           |                          |
|-------------|-----------|--------------------------|
| $S_T = 90$  | -> profit | -4 (max loss = premium)  |
| $S_T = 104$ | -> profit | 0 (breakeven = $K + c$ ) |
| $S_T = 115$ | -> profit | +11                      |

### 2. Box as a loan - $K_1=5000$ , $K_2=5100$ ,

$T = 0.5$  yr,  $r = 5\%$ :

|           |                                           |
|-----------|-------------------------------------------|
| payoff    | = 100 (= \$10,000/box x100)               |
| fair cost | = $100 * e^{-(0.025)} = 97.53$ (~\$9,753) |
| buy @97.0 | -> lend, get 100 -> ~6.3% > 5% (arb)      |
| sell@98.0 | -> borrow @ ~4.1% < 5% (cheap loan)       |
